

Project Proposal

Project Title: Empathetic Emotional Chatbot for Real-Time Mental Health Support

Group Member:

Hammad Saleem

Resource Person: Dr. Daniyal Adeeb

Section: A3

Course: Natural Language Processing

Project Overview

Mental health issues are on the rise, yet many individuals hesitate to seek help due to stigma, inaccessibility, or lack of awareness. To address this challenge, we propose the development of an intelligent, empathetic chatbot that provides real-time mental health support through emotionally aware conversations.

This chatbot will use Natural Language Processing (NLP) to:

- Detect user emotions
- Maintain a record of emotional and symptom history
- Simulate doctor-style responses
- Provide guidance and emotional assistance

It acts as a first layer of support for people experiencing emotional distress, stress, anxiety, or other mental health concerns — offering both conversation and care in a private, non-judgmental environment.

Objectives

- To develop a chatbot that understands and responds to user emotions in real time.
- To provide mental health assistance through simulated conversations.
- To store and reference user emotional/medical history for better future interactions.
- To handle sensitive mental health situations with care and suggest appropriate actions.
- To integrate sentiment and emotion detection using state-of-the-art NLP models.

Key Features

- **Emotion & Sentiment Detection:**

Uses DistilBERT and BART-large-MNLI to detect user mood (e.g., sad, anxious, angry).

- **Real-Time Conversations:**

Responds in a human-like, empathetic tone tailored to the user's emotional state.

- **Simulated Doctor Chat:**

Templates guide users through mental health evaluations and offer supportive feedback.

- **User History Memory:**

Stores past emotional states and conversation history to provide context-aware responses.

- **Emergency Support:**

Detects critical emotional cues and responds with helpful, supportive messages or helpline info.

Tools & Technologies

- Python: Programming the chatbot logic
- Langchain: Building NLP pipelines with memory support

- HuggingFace Transformers: Access to pre-trained models like BART, Flan-T5, DistilBERT
- DistilBERT: Sentiment Analysis
- BART-large-MNLI: Emotion detection via zero-shot classification
- Flan-T5: Text generation for personalized responses
- Prompt Engineering: Custom templates for doctor-style, empathetic, and general responses
- Firebase / JSON / Local Memory: To store emotional and health conversation history

Methodology

1. **Model Selection** - Choose appropriate NLP models for emotion and sentiment detection.
2. **Data Processing** - Process user inputs and classify them as emotional, symptomatic, or general queries.
3. **Response Generation** - Use Flan-T5 and prompt templates to generate appropriate replies.
4. **Memory Handling** - Store and recall user emotional and symptom history.
5. **Evaluation** - Conduct user testing to measure empathy, relevance, and satisfaction.

Target Users

- Students dealing with academic pressure
- Individuals feeling isolated or emotionally low
- Early-stage mental health patients needing friendly support
- Hospitals or clinics looking for supportive chatbot interfaces

Expected Outcomes

- A chatbot capable of providing mental health support in real time
- Intelligent responses based on emotional state and previous chats
- Improved user satisfaction and engagement through human-like conversation
- A foundation for future mental health-focused AI systems

Conclusion

By combining NLP with emotional intelligence, this project aims to develop a meaningful, real-time chatbot that supports users during their mental health challenges. It's an innovative, scalable, and empathetic solution for emotional care — right through conversation.
